## 1. INTRODUÇÃO

Este documento tem por objetivo fornecer informações sobre os parâmetros e critérios adotados para o cálculo do alongamento teórico dos cabos de protensão.

## 2. DESCRIÇÃO

Os cabos foram divididos em seções, e a cada duas seções foi medida a variação angular em elevação e em planta, da esquerda para a direita; no caso de cabos do tipo ativo-passivo e no caso de cabos do tipo ativo-ativo, também foram medidas as variações angulares da direita para a esquerda.

Estas variações angulares foram utilizadas para determinar as tensões devido as perdas por atrito em cada seção. A partir destes valores foi então construído o gráfico mostrando a variação da tensão ao longo dos cabos de protensão para as seguintes curvas:

- $\sigma(x)$  = Curva de perda de tensão no caso de cabo ativo-passivo.
- $\sigma_{\text{esq}}(x)$  = Curva de perda de tensão partindo da esquerda no caso de cabo do tipo ativo-ativo.
- $\sigma_{\text{dir}}(x)$  = Curva de perda de tensão partindo da direita no caso de cabo do tipo ativo-ativo.

Para os cabos do tipo ativo-passivo, foi calculada a área sob a curva  $\sigma(x)$  do gráfico de variação da força ao longo do cabo de protensão e esta área foi dividida pelo comprimento do elemento estrutural, para que se pudesse determinar a tensão média.

Para os cabos do tipo ativo-passivo, foi calculada a área sob a curva  $\sigma_{\text{esq}}(x)$ , da seção inicial do gráfico até a interseção com a curva  $\sigma_{\text{dir}}(x)$  e logo após, foi calculada a área sob a curva  $\sigma_{\text{dir}}(x)$  da interseção com a curva  $\sigma_{\text{esq}}(x)$  até a seção final do diagrama; estas áreas foram somadas e divididas pelo comprimento do elemento estrutural para que se pudesse determinar a tensão média.

Para determinação da força média, foi utilizada a tensão média multiplicada pela área teórica nominal da cordoalha.

### 3. PARÂMETROS DE PROJETO

#### Características das cordoalhas

**Tabela 1 - Características das cordoalhas de sete fios com relaxação baixa - RB**

Categoria	Designação <sup>1)</sup>	Diâmetro nominal da cordoalha mm	Tolerância no diâmetro nominal mm	Área da seção de aço da cordoalha nominal mm <sup>2</sup>			Massa nominal kg/1 000 m	Carga de ruptura mínima kN	Carga a 1% de deformação mínima <sup>2)</sup> kN	Alongamento total na ruptura mínimo <sup>3)</sup> %	Relaxação máxima após 1 000 h <sup>4)</sup> %
				Mínimo	Nominal	Máximo					
RB 190	CP 190 RB 9,5	9,5	+ 0,4 - 0,2	54,9	56,2	57,3	441,0	104,3	93,9	3,5	3,5
	CP 190 RB 12,7	12,7		98,6	100,9	102,9	792,0	187,3	168,6		
	CP 190 RB 15,2	15,2		139,9	143,4	146,3	1126,0	265,8	239,2		
RB 210	CP 210 RB 9,5	9,5		54,9	56,2	57,3	441,0	115,3	103,8		
	CP 210 RB 12,7	12,7		98,6	100,9	102,9	792,0	207,0	186,3		
	CP 210 RB 15,2	15,2		139,9	143,4	146,3	1126,0	293,8	264,4		

<sup>1)</sup> Os três dígitos constantes na designação correspondem ao limite mínimo da resistência à tração na unidade kgf/mm<sup>2</sup>. Para os efeitos desta Norma, considera-se 1kgf/mm<sup>2</sup> = 10MPa

<sup>2)</sup> O valor da carga a 1% de alongamento é considerado equivalente à carga, a 0,2% de alongamento permanente.

<sup>3)</sup> Base de medida: 600 mm mínimo.

<sup>4)</sup> Medida a 20°C com aplicação de carga inicial correspondente a 80% da carga de ruptura conforme NBR 7484. Os resultados de relaxação após 1 000 h podem ser obtidos por extrapolação de ensaios de 100 h de duração.

**NOTA** Recomenda-se para cálculo estrutural a utilização do valor nominal da área.

#### Coeficientes para cálculo das perdas de protensão por atrito

$\mu = 0,50$  entre cabo e concreto (sem bainha);

$\mu = 0,30$  entre barras ou fios com mossas ou saliências e bainha metálica;

$\mu = 0,20$  entre fios lisos ou cordoalhas e bainha metálica;

$\mu = 0,10$  entre fios lisos ou cordoalhas e bainha metálica lubrificada;

$\mu = 0,05$  entre cordoalha e bainha de polipropileno lubrificada;

$k$  é o coeficiente de perda por metro provocada por curvaturas não intencionais do cabo. Na falta de dados experimentais, pode ser adotado o valor 0,01  $\mu$  (1/m).
